

MANUFACTURING: CASE STUDY

Use Case:

Predicting engine block defects and identifying high yield operating regions.

Industry:

Manufacturing

Challenges:

- High Scrap rate
- High rework rate
- High cost

Solution:

- Predictive Model to identify engine blocks that would go on to be defective.
- Prescriptive model to identify high yield operation region.
- Computer vision model to improve QC inspection on sub-surface defects.

Results:

- Halved scrap rate in the first month of deployment.
- 0% external scrap rate within 3 months (first time ever).
- Monthly cost saving of \$36,500

CLIENT

Our client is one of the largest foundries in the Southern Hemisphere. They manufacture and supply large diesel engine blocks to Daimler AG, producing 130,000 engine blocks annually.

The Challenge

The manufacturing sector, just like any other, faces serious challenges with global competition, local costs, cheap imports and productivity concerning local businesses within the sector. Economies are going through a period of significant turbulence, affected by the global financial crisis and the resulting consequences.

Most sector players face similar challenges, increased costs for raw materials are squeezing margins and unless offset by pricing and surcharge increases, manufacturing companies are being strangled.

Companies are also adopting the concept of Corporate Social Responsibility (CSR). While making any decisions they have to keep in mind the effects on the environment and society, which restricts them in certain ways of manufacturing due to emissions and waste generation. Manufacturers now need to use sustainable engineering strategies to step further ahead of their competitors or it may lead to a decline in their brand reputation and cause harm to the environment.

With such challenges plaguing the sector as a whole, our client wanted to find a way to optimise their manufacturing process as well as reduce costs. They were experiencing very high costs due to shipping of defective engine blocks, high internal and external scrap rates and long delays in the manufacturing process due to rework. In a process whereby defects arise through no operational fault, the main challenge was how to reduce such unforeseeable costs.

"I have been using your prescriptive reports to make small calculated adjustments to our system.

The norm for us is 5-6% internal scrap and 10-15% rework. Over a 2 day period we managed to achieve 1% internal scrap and 8% rework.

In the past we have been able to achieve similar results, but we had absolutely no clue what we did to achieve the good result. This time around we have a fairly good idea of what we did to achieve the result.

Thanks for your tremendous efforts and help to take us to the next level."

- Chief Executive Officer

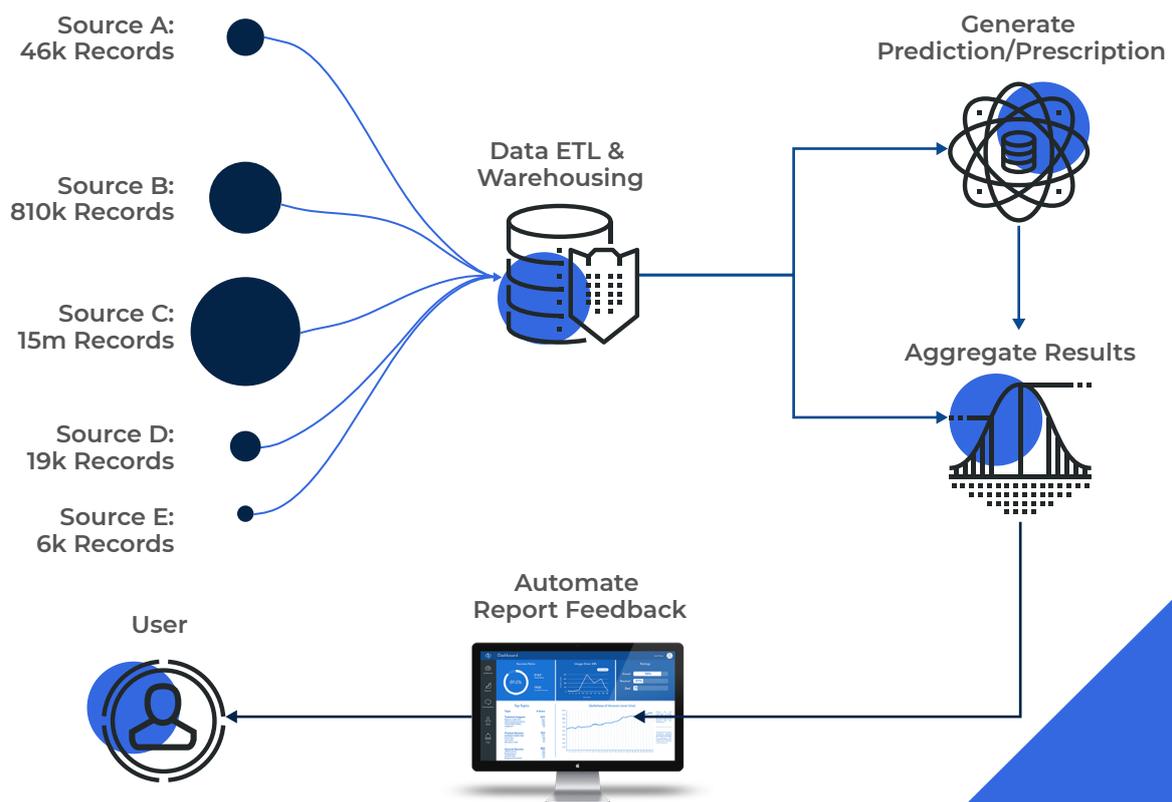

SOLUTION

The solution deployed was DataProphet's OMNI which utilizes advanced forms of supervised and unsupervised machine learning to automatically discover the optimal operating regime for complex, multi-step, industrial processes.

When we started, there was so much data disparity, with the data siloed in different parts of the organization which made it difficult to apply any machine learning capabilities. To that effect, DataProphet started off with a process of data ETL and warehousing of that data across the whole group. The data was obtained from various owners within different business units, in various formats that included excel files, access DB data and CSV data sources. This data was brought into a single view that included 15 months historic production data with 173,000 records and 122,000 unique features.

This data would then go on to be fed into the predictive algorithm in an automated front-end interactive web-based dashboard with a report feedback to the users as shown below:

System Location Agnostic:

RESTful API

About Us

We are an AI company specializing in the development of AI solutions for Industry 4.0—with a specific focus on heavy industries.

Our flagship product OMNI is an AI-enabled process parameter optimization solution that actively reduces scrap and rework. While OMNI Vision, a state-of-the-art computer vision module, further augments OMNI by actively recognizing surface defects on manufactured components — providing an automated quality gate and additional data for OMNI to optimize process parameters.

Our solutions are proven to provide real value for manufacturers, and industry-leading companies rely on us to make the most of their data.

▲ OMNI

DataProphet then went on to develop and deploy a predictive and prescriptive solution powered by state of the art machine learning algorithms to identify engine blocks that would go on to be defective and also identifying the optimum operating regions for maximum yield with variable process parameters. The solution delivers on 3 fronts:

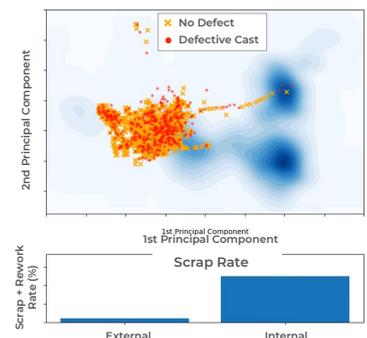

1 - OMNI | PREDICTIVE

Using only the production process data, OMNI would go on to predict most likely defect locations for given process variable values. The defects are always reported per physical location on the castings.

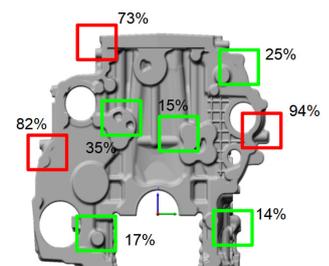

2 - OMNI | PRESCRIPTIVE

Identifying a desirable operating region and generate an understanding of how key process variables differ as a function of yield regions. This would show clear progression across the Principal Component Analysis (PCA) space over time, with surface visualisation of good vs. bad for key variables.

3 - OMNI | VISION

Using region based convolutional neural networks upon your finished products, improve QC inspection tasks by looking for subsurface defects that occur most commonly in the client's products.

▲ RESULTS

For the first time in the history of the company, the client has achieved a 0% external scrap rate. They did not ship a single defective casting meaning no additional cost of returning and also very satisfied customers.

They have had a significant improvement in their QC inspections, faster and more efficient on every product all the time. This means that the additional human element that would have had to perform the tasks manually can now be deployed elsewhere within the factory.

Since deploying DataProphet's OMNI solution, the client has gone on to save millions of rands per month every month, meaning a significant improvement on their bottom line.
